Research in academic medical centers: Two threats to sustainable support

Reductions in federal support and clinical revenue jeopardize biomedical research and, in turn, clinical medicine.

Unstable funding for biomedical research has created a hostile working environment that erodes the time available for investigators to conduct their research, discourages innovative high-risk science, threatens to drive established investigators out of U.S. academic biomedical research, and creates uncertainty for trainees and early-career investigators (1). However, executive directors at academic medical centers wrestle with another concern—one at the systemic level: At any amount of public investment, the cost of the biomedical research enterprise is growing inexorably beyond what available resources can reasonably support (1).

As leaders of U.S. academic medical centers, we are committed to providing high-quality patient care while using our limited resources effectively and efficiently. But we cannot achieve these goals nor meet the health care challenges of an aging and increasingly diverse population without acquiring new knowledge about human health and disease to support the development of creative therapeutic strategies (http://medresearch.tumblr.com). Moreover, our nation’s economy has depended on discovery and invention, the ultimate products of scientific research. Thus, biomedical research is crucial to the U.S. national agenda, and academic medical centers—the proving ground for much of this research—are at particular risk. Persistent constraints on federal funding for biomedical research, including that from the U.S. National Institutes of Health (NIH), threaten to undermine the biomedical research enterprise, and decreasing clinical revenue compounds this threat. Support for the research ecosystem must be predictable and sustainable both for institutions and individual investigators. The U.S. Congress is currently developing the 21st Century Cures Act with the intent of addressing some of these concerns (see http://energycommerce.house.gov/cures).

Unstable funding for biomedical research has created a hostile working environment that erodes the time available for investigators to conduct their research, discourages innovative high-risk science, threatens to drive established investigators out of U.S. academic biomedical research, and creates uncertainty for trainees and early-career investigators (1). ### DIMINISHING RESOURCES FOR SERVING SOCIETY

The remarkable collaboration between the federal government and academic institutions that shares the burden of scientific research and training began after the second World War and was built on the philosophy that new knowledge is a public good. These institutions dedicate resources to grow and sustain research programs (2). However, for the partnership to work effectively, the public’s investment should be commensurate with the expansion of expensive taxpayer-driven research and development priorities in the areas of cancer, diabetes, cardiovascular and neurodegenerative diseases, clinical depression, emerging infectious diseases, and precision medicine as well as with the growth in federal regulation and oversight of research, which has increased substantially over the past half-century.

Aside from federal support, the major sources of funding available to academic medical centers are state governments, technology transfer (significant for only a few institutions) (3), philanthropy, tuition, and clinical income. According to the National Science Foundation (NSF), institution-provided funding for faculty-conducted scientific research has grown faster than any other source of support over the past two decades (4, 5). We estimate that, on average, our respective institutions contribute 53 cents for each dollar (direct and indirect) of all sponsored-research support expended (6).

Some have asserted (1) that federal grants and contracts, by reimbursing indirect (facilities and administrative) costs and faculty salaries, “encourage grantee institutions to grow without making sufficient investments in their own faculty and facilities.” In this context, the term “sufficient” is key. Indirect cost reimbursements compensate for costs already incurred by institutions, although many large research-and education-related expenditures are unallowable for reimbursement under federal cost policies, including the expense of both starting up laboratories and sustaining existing labs (4). Furthermore, the federal reimbursement rate for administrative costs for academic institutions has been capped at 26%, whereas administrative requirements for oversight of sponsored research, protection of human subjects, biosecurity and safety, humane use of animals in research, training in responsible conduct of research, pre- and post-award review and submission, and many other compliance obligations have increased significantly (www.nsf.gov/pubs/2014/nsb1418/nsb1418.pdf). Indeed, the Association of American Medical Col-

Amidst increasingly constrained clinical-reimbursement levels, academic medical centers remain both the major care site and the option of last resort for the most complex and challenging patients. Bearing the cost of outlier patients and of clinical care provided as part of clinical research represents another contribution to the public good. Moreover, academic medical centers treat a disproportionately large share of individuals without adequate health insurance or sufficient means to pay for care. In 2012, the median charitable health care provided by AAMC-member teaching hospitals was $65 million (8), which may or may not decline, depending on how the new landscape associated with the Affordable Care Act and other policy developments evolves.

Recommendations to stabilize the biomedical research enterprise must identify new resources, policies, and business models for sustaining such research, not simply shuffle financial responsibilities within the current model. We must reinvigorate the federal-academic partnership for research across all sciences. The convergence of many essential fields around biology, as highlighted in the recent report entitled A New Biology for the 21st Century, offers opportunities for academic partners to serve social objectives (www.nap.edu/catalog/12764/a-new-biology-for-the-21st-century).

With regard to sustainability, both the federal government and our institutions must recognize that we have made a huge investment in developing young scientists that they can launch independent research careers, and if we are to recoup our investment, these careers must be sustained at least until failure is evident. The draft 21st Century Cures Act includes a section devoted to emerging scientists, in order to promote increased support of investigators at the early stages of their independent careers. Academic medical centers must join with NIH to strengthen support for the training and early-stage research of physician-scientists, who carry out a singular mission in biomedical research (9); promote stable careers for our most creative principal investigators; and provide more stable support mechanisms for staff scientists (10). Furthermore, we must create career paths that at least partially decouple research activity from the trainee enrollment and develop training models that recognize that many trainees go on to a variety of important nonacademic careers, in addition to academic ones.

A sustainable business model with predictable growth in appropriations to NIH and other research sponsors, indexed to the relevant rate of inflation and projected over 3 to 5 years, would allow both federal and academic institutions to plan their investments in human and physical capital and manage expenditures more strategically than is possible in the face of annual funding uncertainty. The 21st Century Cures Act draft authorizes (but does not appropriate) increases of ~4.6% for fiscal years 2016 to 2018. In addition, the draft proposes the appropriation of an additional $2 billion per

FOCUS

year for fiscal years 2016 to 2020 through the creation of an “Innovation Fund,” the uses for which are still under discussion. This fund would be in addition to the regular NIH appropriation.

Academic medical centers are committed to leading the national effort to provide high-quality care to all Americans. But achievement of this goal requires a stable economic platform that supports the full spectrum of biomedical and engineering research, from the investigation of fundamental mechanisms of human biology and behavior to the translation of such discoveries to patients, communities, and populations. In short, to provide next-generation health care solutions, we require 21st-century policies that support modern scientific research and development. Because research in academic medical centers requires both federal and institutional support—the latter of which depends on clinical revenue—scientists, administrators, and policy-makers must collaborate effectively to address both threats.
